Why Ensemble Learning?

```
prediction.accuracy.rate <- function(no.classifier=1, accuracy.rate=0.5) {</pre>
   c(no.classifiers=no.classifier,
     at.least.one.accuracy=1-(1-accuracy.rate)^no.classifier)
> prediction.accuracy.rate()
       no.classifiers at.least.one.accuracy
                   1.0
                                          0.5
> t(sapply(1:10, prediction.accuracy.rate))
      no.classifiers at.least.one.accuracy
 [1,]
                                  0.5000000
 [2,]
                                  0.7500000
 [3,]
                                  0.8750000
 [4,1
                                  0.9375000
 [5,]
                                  0.9687500
 [6,]
                                  0.9843750
 [7,]
                                  0.9921875
 [8,]
                                  0.9960938
 [9,1
                                  0.9980469
[10,]
                   10

```

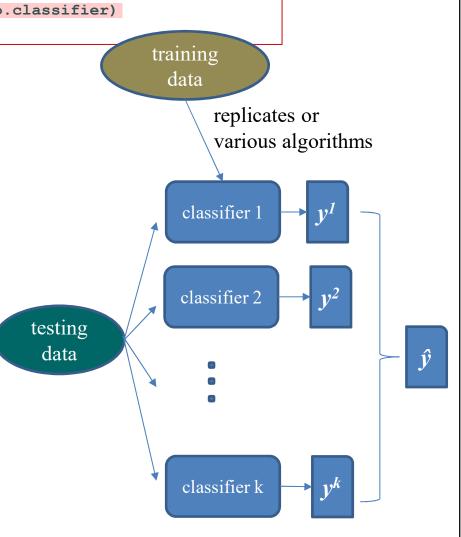

Two major benefits of Ensemble models:

- Better prediction.
- More stable model.

自助法、拔靴法 Bootstrap Methods

 Bootstrapping is a statistical method for estimating the sampling distribution of an estimator by sampling with replacement from the original sample, of the same size as the original sample.

Bradley Efron 1938~ Department of Statistics, Stanford University

1993

2016

Efron: Bootstrap Methods: Another Look at the Jackknife - Project Euclid https://projecteuclid.org/euclid.aos/1176344552 ▼ 翻譯這個網頁 由 B Efron 著作 - 1979 - 被引用 16424 次 - 相關文章 The Annals of Statistics ... Bootstrap Methods: Another Look at the Jackknife ... The jackknife is shown to be a linear approximation method for the bootstrap.

Bagging: Bootstrap Aggregating

http://blog.csdn.net/bymaymay/article/details/77824574

- Breiman, L. (1996). Bagging predictors, Machine Learning, Vol. 26, pp. 123-140.
- Freund, Y. and Schapire, R. E. (1996). Experiments with a new boosting algorithm, Proceedings of the Thirteenth International Conference, Machine Learning.

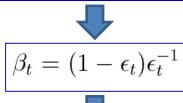

Boosting

a bootstrap sample $\mathcal{L}_t^{(B)}$ error ϵ_t of classifier $\varphi_t(\mathbf{x})$

$$\epsilon_t = \sum_{\{i: \varphi_t(x_i) \neq y_i\}} W_{x_i}^{(t)}.$$

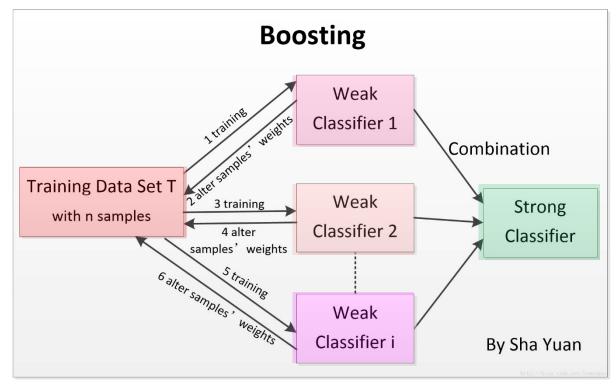

$$W_{x_i}^{(t+1)} = \frac{W_{x_i}^{(t)} \beta_t^{d(i)}}{\sum_i W_{x_i}^{(t)} \beta_t^{d(i)}},$$

boosted classifier

http://blog.csdn.net/bymaymay/article/details/77824574

d(i) = 1 if ith case is classified incorrectly,

d(i) = 0, otherwise

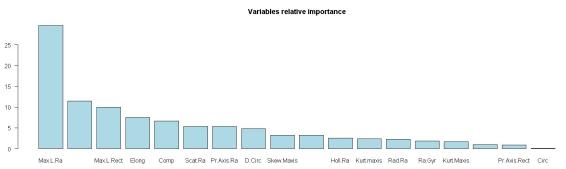

$$arphi_B(x_i) = arg \; max_j \sum_{t=1}^T \log eta_t I[arphi_t(x_i) = j]$$
 Ad-Boost.M1 (Freund and Schapire, 1996)

不平衡資料問題

The Imbalanced Data Problem

- A dataset is said to be unbalanced when the class of interest (minority class) is much rarer than normal behaviour (majority class).
- Example: 5% of the target class represents fraudulent transactions,
 95% of the target class represents legitimate transactions.
- Most learning systems are not prepared to cope with unbalanced data and several techniques have been proposed.

http://www.srutisj.in/blog/research/statisticalmodeling/balancing-techniques-for-unbalanced-datasets-in-python-r/

unbalanced

Racing for Unbalanced Methods Selection

```
Re-balance or remove noisy instances in unbalanced datasets.
     ubBalance {unbalanced}
Usage
     ubBalance(X, Y, type="ubSMOTE", positive=1,
                   percOver=200, percUnder=200,
                   k=5, perc=50, method="percPos", w=NULL, verbose=FALSE)
Arguments
     x: the input variables of the unbalanced dataset.
     Y: the response variable of the unbalanced dataset.
     type: the balancing technique to use (ubOver, ubUnder, ubSMOTE, ubOSS, ubCNN, ubENN,
     ubNCL, ubTomek).
     positive: the majority class of the response variable.
     percover: parameter used in ubSMOTE
     percUnder: parameter used in ubSMOTE
     k: parameter used in ubOver, ubSMOTE, ubCNN, ubENN, ubNCL
     perc: parameter used in ubUnder
     method: parameter used in ubUnder
     w: parameter used in ubUnder
     verbose: print extra information (TRUE/FALSE)
```

```
ubSMOTE {unbalanced}: synthetic minority over-sampling technique

Usage
ubSMOTE(X, Y, perc.over = 200, k = 5, perc.under = 200, verbose = TRUE)
```

Other R packages: imbalance: Preprocessing Algorithms for Imbalanced Datasets, Imbalanced Classification in R: ROSE (Random Over Sampling Examples) and DMwR (Data Mining with R).

The Balancing Technique

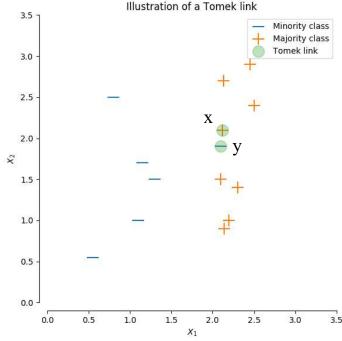

- ubOver: replicates randomly some instances from the minority class in order to obtain a final dataset with the <u>same number of instances</u> from the two classes.
- ubUnder: removes randomly some instances from the majority (negative) class and keeps all instances in the minority (positive) class in order to obtain a more balanced dataset.
- ubcnn: Condensed Nearest Neighbor selects the subset of instances that are able to correctly classifying the original datasets using a one-nearest neighbor rule.
- **ubenn**: **Edited Nearest Neighbor** removes any example whose class label differs from the class of at least <u>two of its three nearest neighbors</u>.
- **ubNCL**: Neighborhood Cleaning Rule modifies the Edited Nearest Neighbor method by increasing the role of data cleaning.
 - Firstly, NCR removes negatives examples which are misclassified by their 3nearest neighbors.
 - Secondly, the neighbors of each positive examples are found and the ones belonging to the majority class are removed.

The Balancing Technique

ubTomek: finds the points in the dataset that are tomek link using 1-NN and then removes only majority class instances that

are tomek links.

x's nearest neighbor is y y's nearest neighbor is x x and y are different classes

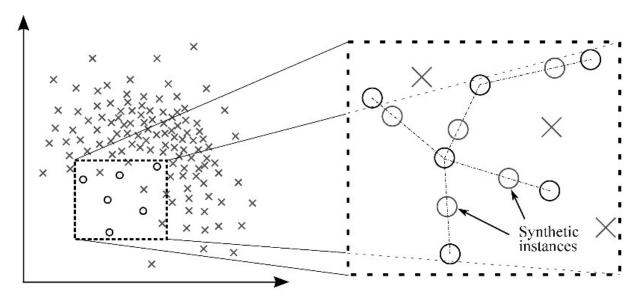

http://contrib.scikit-learn.org/imbalanced-learn/stable/auto examples/under-sampling/plot illustration tomek links.html

 uboss: One Side Selection is an undersampling method resulting from the application of Tomek links followed by the application of Condensed Nearest Neighbor.

The Balancing Technique

• ubSMOTE: synthetic minority over-sampling technique generates new examples by filling empty areas among the positive instances.
